CORROSION INHIBITION BY AN AQUEOUS EXTRACT OF

ALOE VERA (L.) BURM F. (LILIACEAE)

V. Sribharathy[a]*, Susai Rajendran [a,b]*, P. Rengan[ c], R. Nagalakshmi[ d]

Keywords: carbon steel, corrosion inhibition, plant extract, aloevera, seawater, green inhibitor.

An aqueous extract of Aloe vera (L) Burm f. (Liliaceae) has been used as a corrosion inhibitor in controlling corrosion of carbon steel immersed in sea water. Weight loss method reveals that 4ml of the extract provide 98% inhibition efficiency. The protective film has been analyzed using Fourier transform infrared (FTIR) spectroscopy and fluorescence spectroscopy. Electrochemical studies such as potentiodynamic polarization and alternating current impedance spectra have been used to find the mechanistic aspects of corrosion inhibition.

Introduction

Plant extracts have become important as environmentally acceptable, readily available and renewable source for wide range of inhibitors. In general, the plant extracts are of inhibitors with high inhibition efficiency and of non toxicant. El-Etre et al. investigated Khillah extract for the corrosion inhibition of SX 316 steel in acid media. Lawsonia extract was studied for effect against acid induced corrosion of metals. Opuntia extract was investigated for the corrosion of Aluminum in acid medium and vanillin for the corrosion of mild steel in acid media. Yan Li et al Berberine isolated an alkaloid from Captis studied for its anticorrosion effect for mild steel corrosion in H2SO4 medium. Fabrizio Zucchi and Ibrahim Hashi Omar isolated an alkaloid from Captis studied for its anticorrosion effect for mild steel corrosion in H2SO4 medium. The present work investigated the inhibition efficiency of an aqueous extract of plant material, Aloe vera (L) Burm f. (Liliaceae) extract, in controlling corrosion of carbon steel (CS) immersed in sea water in the absence and presence of inhibitor, using mass loss method, analyzed the protective film by Fourier transform infrared (FTIR) spectroscopy and fluorescence spectroscopy, and proposed a suitable mechanism of corrosion inhibition, based on the results of the above studies and potentiodynamic polarization and the alternating current (AC) impedance spectra.

Experimental

Preparation of plant extract

An aqueous extract was prepared by grinding 10 g of fresh extract of aleo vera (mannose-6-phosphate) gel, filtering and making up to 100 ml using double distilled water.

Preparation of specimens

Carbon steel specimens (0.0267% S, 0.06% P, 0.4% Mn, 0.1% C and the rest iron) of dimensions 1.0 cm x 4.0 cm x 0.2 cm were polished to a mirror finish and degreased with trichloroethylene.

Weight loss method

Relevant data of sea water used in the study, are given in Table1. Three mild steel specimens were immersed in 100 ml of sea water containing various concentrations of the inhibitor for one day. The weight of the specimens before and after immersion were determined using Shimadzu balance, model AY 62. The corrosion products were cleansed with Clarke’s solution.

The inhibition efficiency ($IE$, %) was then calculated using the equation

$$IE = 100 \left(1 - \frac{W_2}{W_1}\right)$$  \hspace{1cm} (1)

where

$W_1$ = corrosion rate in the absence of the inhibitor

$W_2$ = corrosion rate in the presence of the inhibitors

Surface Examination

The carbon steel specimens were immersed in various test solutions for a period of one day, taken out and dried. The nature of the film formed on the surface of metal specimens was analyzed by FTIR spectroscopic study.

FTIR Spectra

FTIR spectra were recorded in a Perkin – Elmer 1600 spectrophotometer. The film was carefully removed, mixed thoroughly with KBr made in to pellets and FTIR spectra were recorded.

The fluorescence spectra of the film formed on the Carbon Steel samples recorded with a Hitachi F-4500 fluorescence spectrophotometer.

Potentiodynamic Polarization

The polarization studies were carried out in a three electrode cell consisting of mild steel as working electrode (WE), a platinum wire counter electrode (CE), and a saturated calomel electrode reference electrode were used for measurements\textsuperscript{35}. All the potential values reported here was VS SCE (Scheme1).

The working electrode was mechanically polished on various grades of emery sheet, rinsed with double distilled water, degreased with trichloroethylene. Potentiodynamic polarization curves were recorded using an H & CH electrochemical work station impedance analyzer model CHI 660A provided with iR compensation option. Polarization curve measurements were carried out at scan rate of 0.01 V s\textsuperscript{-1}.The exposed area (1 cm\textsuperscript{2}) was mechanically polished with a series of emery sheets of variable grade. The samples were washed thoroughly with double distilled water before insertion in the cell. During the polarization study, the scan rate was 0.01 V s\textsuperscript{-1}; hold time at EF was 0 s and quiet time was 2 s.

AC impedance measurements

The instrument used for polarization was used for AC impedance study also. The cell set up was the same as that had been used for polarization measurements. The real part and imaginary part of the cell impedance were measured in ohms at various frequencies. The values of charge transfer resistance, $R_{ct}$, and the double layer capacitance, $C_{dl}$ were calculated.

$$C_{dl} = \frac{1}{2\pi R_s f_{\text{max}}}$$  \hspace{1cm} (3)

where

$R_s$ - Solution resistance,

$f_{\text{max}}$ - maximum frequency.

AC impedance spectra were recorded with de potential $E = 0$ V, in the frequency range $1x10^5$ - 10 Hz, amplitude = 0.005 V, and quiet time = 2 s.

Result and Discussion

Weight loss studies

Table 1 shows the values of corrosion rates and inhibition efficiencies obtained from weight loss measurements of different concentrations of aleo vera extract. 4 ml of the aleo vera offered 98 % corrosion inhibition efficiency to carbon steel immersed in 100 ml sea water. When the concentration of aleo vera was increased the inhibition efficiency decreased. This is due to the fact that when higher concentrations of aleo vera are added the protective film Fe$^{2+}$-mannose-6-phosphate complex formed on the metal surface goes into the solution and thus destroying the protective film. It may be considered that the protective film formed may go into transpassive state, where the film is broken\textsuperscript{36}.

Analysis of polarization curves

The polarization study has been used to investigate the formation of protective film on metal surface 37-41. The polarization curves of carbon steel immersed in various solutions are shown in Fig 1. The corrosion parameters such as corrosion potential ($E_{corr}$), cathodic Tafel slope and anodic Tafel slope were determined from $E$ vs log$I$ plots. When Aloe vera is added to the solution, the corrosion potential is shifted towards the anodic side, indicating that the Aloe vera controls the anodic reaction. The Linear polarization resistance ($LPR$) value increases from 51.67 x 10$^2$ to 76.01 x 10$^2$ ohm cm$^2$. This suggests that a protective film is formed on the metal surface.

Fourier Transfer Infrared Spectra

The main constituent of aloe vera extract is mannose-6-phosphate\(^47\). The structure of mannose-6-phosphate is shown in Scheme 3. It contain phosphate group, hydroxyl group and ring oxygen.

![Scheme 3. Mannose-6-phosphate](image)

The aloe vera extract was evaporated to dryness to a solid mass. Its FTIR spectrum is shown in Fig 3a. The \(-\text{OH}\) stretch appeared at 3410 cm\(^{-1}\). The aliphatic \(-\text{CH}_2\) stretching frequency appeared at 2936 cm\(^{-1}\). The ring oxygen stretching frequency appeared at 1237 cm\(^{-1}\). Phosphate stretching frequency appeared at 1060 cm\(^{-1}\)\(^48-49\).

The FTIR spectrum of the protective film formed on the surface of the metal after immersion in the aqueous solution containing sea water and sea water containing 4ml of aloe vera is shown in Fig 3b. It is found that the \(-\text{OH}\) stretch has shifted from 3410 cm\(^{-1}\) to 3433 cm\(^{-1}\). The aliphatic \(-\text{CH}_2\) stretching frequency shifted from 2936 cm\(^{-1}\) to 2943 cm\(^{-1}\). Phosphate stretching frequency shifted from 1060 cm\(^{-1}\) to 1100 cm\(^{-1}\). The ring oxygen stretching frequency shifted from 1237.20 cm\(^{-1}\) to 1237.92 cm\(^{-1}\). It is inferred that the active principle has coordinated with through the oxygen atom of P-O groups, OH group and ring oxygen resulting in the formation of Fe\(^{2+}\)-mannose-6-phosphatocomplex.

UV-Visible adsorption spectra

The UV-Visible adsorption spectrum of aqueous solution of aloe vera is shown in Fig 5a Peaks appear at 255 nm, 266 nm, 298 nm and 353 nm. When the Fe\(^{2+}\) (Freshly prepared FeSO\(_4\) H\(_2\)O Solution) is added to the aqueous solution of aloe vera peak appear at 227 nm\(^50\). This is due to Fe\(^{2+}\) - mannose-6-phosphate complex formed in solution.
Fluorescence spectra
The fluorescence spectrum ($\lambda_{ex} = 227$ nm) of the solution containing aloe vera extract and Fe$^{2+}$ is shown in Fig 6a. A peak appears at 252 nm. This is due to Fe$^{2+}$-mannose-6-phosphate complex formed in solution. The fluorescence spectrum ($\lambda_{ex} = 227$nm) of the film formed on the surface of the metal after immersion in the sea water and 4ml of aloe vera extract is shown in Fig 6b. The peak appeared at 252 nm confirming the presence of Fe$^{2+}$-aloe vera extract complex formed on the metal surface$^{51}$.

**Figure 6.** Fluorescence spectra, a) sea water; b) sea water + 4ml aloe vera extract

Conclusions
The main constituent of the aqueous extract of aloe vera is mannose-6-phosphate. An aqueous extract of aloe vera has excellent IE in controlling corrosion of carbon steel in aqueous solution containing sea water. The protective film consists of Fe$^{2+}$-aloe vera complex. It is found to be UV-fluorescent. The formulation controls the anodic reaction predominately.
