NON-EXISTENCE OF SECONDARY COORDINATES OF INTERSECTS

V. I. Krupyanko

Keywords: non-competitive enzyme inhibition; corrected coordinates for calculation of enzyme inhibition and enzyme activation constants; secondary coordinates of intersects

The analysis of algebraic forms of corrected equations for the calculation of constants of enzyme inhibition ($K_i$) and activation ($K_a$) have shown that the secondary intersects coordinates ($1/V'$; $i$) may be use for calculation only $K_{III}$ constants of non-competitive enzyme inhibition. A few examples of application of corrected coordinates are given in the present research article.

Introduction

In the already available reports 1-4 the possibilities of plotting the ($L_a$) vectors of inhibited enzymatic reactions and ($L_a$) vectors of activated enzymatic reactions in the three-dimensional $K'_mV'I$ coordinate system 1 and also of using the properties of such vectors for plotting the parametric classification of types of enzymatic reactions 2 and the deduction of equations for calculation of initial rates of activated ($v_a$) and inhibited ($v_i$) enzymatic reactions and also of equations for calculation of ($K_i$) constants of enzyme activation and ($K_i$) constants of non-trivial types of enzyme inhibition unavailable in usual practice are considered.

The present paper is dedicated to the possibility of using the secondary coordinates of slopes that take into account the orthogonal projections of $L_i$ vectors of enzyme inhibition and $L_a$ vectors of activated enzymatic reactions on the basic ($\sigma_0$) plane of the $K'_mV'I$ coordinate system (Figure 1) for calculation of $K_i$ and $K_a$ constants.

Correction of the coordinates of slopes and intersects for calculation of constants of enzyme inhibition and activation

Deduction of equations for calculation of $K_i$ constants of enzyme inhibition and $K_a$ constants of enzyme activation 4 that take into account the position of orthogonal projections of $L_i$ vectors of enzyme inhibition and $L_a$ vectors of activated enzymatic reactions on the basic ($\sigma_0$) plane (Figures 1 and 2) opens up the possibility of plotting the secondary (corrected) coordinates of slopes for more accurate estimation of such constants.

Example 1

Calculation of the $K_{III}$ constant of enzyme inhibition. Let us consider the inhibitory effect of increasing concentrations of sodium molybdate (Na$_2$MoO$_4$·2H$_2$O) on initial rates of pNPP cleavage catalyzed by calf alkaline phosphatase (EC 3.1.3.1).
Non-existence of secondary coordinates of intersects

Enzyme Activity Assay

Reactions were performed in 0.05 M Tris-HCl buffer (pH 9.0) at ionic strength 0.1 by NaCl of high purity under constant mixing in a thermostat at 37 °C. The final concentrations of pNPP were varied within 2.94×10⁻⁵ - 9.8×10⁻⁵ M, the concentration of enzyme was constant 1.13 µg mL⁻¹ and that of (10⁻⁴ M) Na₂MoO₄·2H₂O was varied within 0.0625 – 0.25 (Figure 3A). The course of pNPP cleavage by calf alkaline phosphatase was recorded by a CF-4 DR double-beam spectrophotometer (Optica Milano, Italy). Reactions were registered at the wavelength (+ΔD₄₀₀) of solution containing substrate, enzyme and inhibitor against the solution of the same composition, but without the enzyme.

Initial reaction rates of pNPP cleavage were determined by the slope angles of tangents to initial segments of curves representing a course of reaction change in not less than five sets of parallel experiments.

The kinetic and parameters of calf alkaline phosphatase inhibition were calculated by plots in the (1/v, 1/S) coordinates of Lineweaver-Burk by using the program SigmaPlot, version 2000 (USA). Root-mean-square deviations at five-fold determination were as follows: 1/v = ±2.5 %; Kₘ and V = ± 7.5 %, Kᵢ (and Kₛ) = ± 10 %.

Results

As clearly observed from the results given in Figure 3A and Table 1 the increasing concentrations of MoO₄²⁻ exhibit all the features of the biparametrically coordinated Iᵢ type (Kₘ'>Kₘ, V'<V, i>0) of enzyme inhibition and hence, we shall use (Eq. 1 of Table 2):

\[ K_{iI} = \frac{i}{\left( \frac{K_m - K_{m0}^0}{K_m^0} \right)^2 + \left( \frac{V^0 - V'}{V'} \right)^2} \]

* A – according to Eq. (1), it is a dimensionless value.

Table 1. Inhibitory effect of increasing concentrations of anions MoO₄²⁻ on calf alkaline phosphatase

Substitution of appropriate parameters in this equation yields the following values of the constant of enzyme inhibition: Kᵢ (10⁻⁴ M): 0.523, 0.551 and 0.646 – by the first, second and third concentration of MoO₄²⁻.

However, Eq. (1) provides for another more preferable option for calculation of such constants: plotting of dependencies of change in the values of denominators of this equation in the coordinates (A,i), where Kᵢ of enzyme inhibition can be calculated by the slope angle (tg a) of the experimental line (Figure 3B):

\[ A = \frac{1}{K_{ii}} \]

(2)

to the abscissa axis:

\[ K_i = \frac{1}{\sqrt{\gamma a}} \]

(3)

where

\[ A \] – a course of change of the denominator of Eq. (1) on increasing concentrations of MoO₄²⁻.

Data analysis of Figure 3A by using the program Sigma Plot, version 2000 (USA) shows:

![Figure 3B](image.png)

**Figure 3B.** Dependence of A parameters of Eq. (2) (Figure 3A) on increasing concentration of anions MoO₄²⁻ in the coordinates (A,i).
This gives the following (average) value of the $K_{ii}$ constant of calf alkaline phosphatase: $K_{ii}=1/(1.575\times10^8\text{ M}^{-1})=0.635\times10^{-4}\text{ M}$.

At analogous data analysis (Figure 3A) a technique of plotting the dependencies of change in the ratio $K'_{ii}/V'$ of inhibited enzymatic reactions on molar concentrations of inhibitor $i_{ii}$ in the secondary coordinates of slopes ($K'_{ii}/V'$; $i$) and the coordinates of intersects ($1/V'$; $i$) used for calculation of the $K_{ii}$ - slope constant and $K_{ii}$ - intersects constant in enzyme inhibition is widely employed.\textsuperscript{7-11}

Plotting the dependencies of change in the ratio $K'_{ii}/V'$ (Figure 3A) on the molar concentrations of $i_{ii}$ in the coordinates of slopes ($K'_{ii}/V'$; $i$) (see Figure 3C, line 2) for calculation of $K_{ii}$ - slope-constant and the coordinates of intersects ($1/V'$; $i$) (Figure 3C, line 1) for calculation of $K_{ii}$ - intersect-constant of enzyme inhibition.

This gives the following values: $K_{ii}=0.275\times10^{-4}\text{ M}$ in the first case and $K_{ii}=0.715\times10^{-4}\text{ M}$ – in the second case (Figure 3C), which neither in the second case nor in the first one would correspond the actual value: $K_{ii}=0.635\times10^{-4}\text{ M}$ calculated by Eqn. 3.

Deviation between the values of constants $K_{ii}$ and $K_{ii}$, $K_{ii}$ can be explained as: at calculation of the latter, the lengths of orthogonal projections of $L_{ii}$ vectors on the basic $e_0$ plane in the $K'_{ii}/V'/I$ coordinate system (Figures 1 and 2) were not taken into account, and besides this, as shown below (Example 3), the coordinates of intersects ($1/V'$; $i$) are a simplified form ($K'_{ii}/V'$; $i$) of the coordinates of slopes (Table 3), and plotting the dependencies in these coordinates does not take into account changes $K'_{ii}$ parameters of the biparametrical reactions, to which the data of Figure 3A are referred.

Examples of using the coordinates ($K'_{ii}/V'$; $i$) and ($1/V'$; $i$) to data analysis of such type (Figure 3A) of enzyme inhibition are numerous in literature.\textsuperscript{5,11}

The $K'_{ii}$ and $V'^{0}$ parameters of initial reaction ($i=0$, or $a=0$) are present in all the equations of Table 2 used for calculation of $K_{ii}$ and $K_{ii}$ constants of enzyme inhibition and activation. This may lead to difficulties, for example, in search of a response to a query as to how shall we use these equations, if the values $K'_{ii}$ and $V'^{0}$ parameters of initial reaction have not been determined? Such data are often available in experimental part of the reports in literature.\textsuperscript{7,12,14,16}

The best possible answer here follows from analysis of plots of Figures 3A and 3B. Thus, as clearly observed from Figure 3B, the slope angles ($\tan a$) of rectilinear segments of dependencies $A= f(i)$ will coincide by tested intervals ($\Delta i$) of the concentrations of inhibitor: for $\Delta (i_1 – 0) = (0.0625 – 0) \times10^{-4}\text{ M}$, where: $K_{ii(0)}=0.523\times10^{-4}\text{ M}$, for $\Delta (i_2 – i_1) = (0.125 – 0.0625) \times10^{-4}\text{ M}$, where $K_{ii(2)}=0.551\times10^{-4}\text{ M}$, for $\Delta (i_3 – i_2) = (0.25 – 0.125) \times10^{-4}\text{ M}$ where $K_{ii(3)}=0.646\times10^{-4}\text{ M}$ (see Table 1). Such coincidence of the results is evident.

**Example 2**

Calculation of the $K_{Vii}$ constant of enzyme activation. Earlier, the activating effect of arginine-containing activator (ArgA), on initial rates of $P_9$ polyphosphate cleavage by vacuolar polyphosphate hydrolase from the fungus, *Neurospora crassa* (E.C. 3.6.11) which exhibits the maximum activity at pH 6.4. The conditions of enzyme isolation and study of its activity are given in the reference.\textsuperscript{12}

**Results**

The results of this experiment presented in Figure 4A show that in the presence of 1.1 $\mu$M activator the activity of $P_9$ polyphosphate cleavage by vacuolar polyphosphate hydrolase under study had the following parameters: $K'_{ii}=3.810\times10^{-4}\text{ M}$, $V'^{0}=2.110\mu\text{E}\cdot\text{min}^{-1}$; in the presence of 2.20 $\mu$M – by $K'_{ii}=4.359\times10^{-4}\text{ M}$, $V'^{0}=2.773\mu\text{E}\cdot\text{min}^{-1}$; in the presence of 3.3 $\mu$M – parameters: $K'_{ii}=4.836\times10^{-4}\text{ M}$, $V'^{0}=3.494\mu\text{E}\cdot\text{min}^{-1}$.

</table>
It satisfies type $V_{ia}$ of enzyme activation (line 10, Table 3) and hence, Eqn. 10 of Table 2, is applicable here for calculation of $K_{V_{ia}}$ constant of enzyme activation, as the parameters of initial reaction ($K_m^{0}$ and $V_0^{0}$) in this case were not determined, because of weak enzyme activity in the absence of activator.

Use of this equation gives the following values of constants of polyphosphatase hydrolase activation: $K_{V_{ia}}=3.182 \text{ } \mu\text{M} – \text{in the interval ArgA (2.2–1.1=1.1) } \mu\text{M}$ and $K_{V_{ia}}= 3.103 \text{ } \mu\text{M} – \text{in the interval ArgA (3.3–1.1 = 2.2) } \mu\text{M}$, where $K_{m(2.2)}=K_{m(1.1)}=K_{m}^{0}$ and so on. 

By having marked according to the equation:

$$K_{ia} = \frac{1}{tga} = \frac{1}{A/a} = \frac{a}{A}$$

(4)

the numerical values of $A$ denominators by intervals of tested concentrations of ArgA. One shall obtain that the values of $A$ parameters are in the following functional dependence on the intervals of tested concentrations of activator (Figure 4B):

Hence, the average value of this constant (by intervals of ArgA concentrations as activator) shall be the value:

$$K_{V_{ia}} = 1/b(1) = 1/3.2227 (\mu\text{M})^{-1} = 0.3103 \text{ } \mu\text{M},$$

(5)

Figure 4B. Dependence of $A$ parameters of Eqn. 5 (Figure 4A) on increasing concentrations of ArgA in the coordinates $(A; [\text{ArgA}])$. Designation: the intervals of tested concentrations ArgA were 1.1 and 2.2 $\mu$M.

where, $b(1) = 3.2227$ – a parameter of the subprogram statistics of the computer program SigmaPlot, version 2000.

Probably, this technique may also be used in the case of single intervals of $\Delta a$ and $\Delta i$ parameters of both the biparametrical and monoparametrical $K_a$ and $K_i$ constants of enzyme inhibition and activation (Table 2).

At data analysis of the $V_{ia}$ type of enzyme activation (the positions of plots are typical of Figure 4A).
The many authors\textsuperscript{7,13-16} used to plot such dependences of a course of change of the slope angles (tg $\alpha_i$) and the intersection points ($1/V'$) of the ordinate axis as a function of reverse concentrations of activator $1/a$ in the coordinates of: $(tg \alpha_i, 1/a)$ slopes and $(1/V', 1/a)$ intersects. It is incorrect. Plotting the dependencies of change of $K_{m}'/V'$ on $1/a$ in the coordinates of slopes ($K_{m}'/V'$; $1/a$) and coordinates of intersects ($1/V'$; $1/a$) does not take into account symmetric counter-directivity of effects of enzyme activation to $\rightarrow$ enzyme inhibition, which is so evident at the comparison of the positions of one-type enzyme inhibition, which is so evident at the comparison of counter-directivity of effects of enzyme activation to 

The concentration of pNPP in the experiment was varied within $0.294 \times 10^{-5} - 0.98 \times 10^{-5}$ M, the concentration of enzyme was kept constant $1.13 \mu$g mL$^{-1}$. The other conditions are the same as in Example 1.

**Results**

The results of study showed that the kinetic parameters of initial reaction ($K_{m}^0=5.31 \times 10^{-5}$ M, $V_{m}^0=9.321 \mu$mol·min$^{-1}$ µg protein$^{-1}$) in the presence of $0.25 \times 10^{-5}$ M K$_3$Fe(CN)$_6$ change as follows: $K_{m}^0=5.23 \times 10^{-5}$ M, $V_{m}^0=8.158 \mu$mol·min$^{-1}$ µg protein$^{-1}$, in the presence of $0.5 \times 10^{-3}$ M K$_3$Fe(CN)$_6$: $K_{m}^0=5.31 \times 10^{-5}$ M, $V_{m}^0=5.70 \mu$mol·min$^{-1}$ µg protein$^{-1}$, and in the presence of ($1 \times 10^{-3}$ M) K$_3$Fe(CN)$_6$ $- K_{m}^0=5.27 \times 10^{-5}$ M, $V_{m}^0=7.085 \mu$mol·min$^{-1}$ µg protein$^{-1}$ (Figure 5A).

It satisfies all the features ($K_{m}^0=K_{m}'$, $V_{m}<V_{m}^0$, $i=0$) of the catalytic $III_i$ type of enzyme inhibition. As seen from Figure 5A, lines 1, 2 and 3 of inhibited reactions go above line 0 of initial reaction in the first quadrant of the ($V'$) coordinates in the point ($-1/K_{m}'$, 0) located on the continuation of the abscissa axis. The positions of lines 1, 2 and 3 (Figure 5A) are typical to such of lines III and 0 (Figure 3 in Table 3); hence, for calculation of $K_{m}'$, constant of enzyme inhibition we shall use the equation:

$$K_{m}' = \frac{i}{V^0/V' - 1}$$  \hspace{1cm} (6)

of (Table 2, line 3).\textsuperscript{4}

To calculate the value of the constant of enzyme inhibition independently of deviations due to sue of separate (individual) concentrations of K$_3$Fe(CN)$_6$, it is also desirable to employ already above-described techniques (Examples 1 and 2) – it is study of effect of increasing concentrations of inhibitor on initial rates of substrate cleavage by plotting dependences in one (or several) variants of the secondary coordinates of slopes, which proceed from transformation of Eq. (6). It is easy to see that in the ($V'/V; i$) coordinates of slopes the experimental line:

$$\frac{V'}{V} = \frac{1}{K_{m}'} \cdot i + 1$$  \hspace{1cm} (7)

explained by this equation (Figure 5B, line 2) or in the ($1/V; i$) variant of the same coordinates of slopes the line:

$$\frac{1}{V} = \frac{1}{V^0} \cdot \frac{1}{K_{m}'} \cdot i + \frac{1}{V^0}$$  \hspace{1cm} (8)

(Figure 5B, line 1) shall intersect the continuation of the abscissa axis of molar concentrations of inhibitor in the point: $-i_{m} = K_{m}''$.

Analysis of the positions of the intersection points of the abscissa of Figure 5A using the subprogram Statistics of the computer program SigmaPlot, version 2000 (USA) gives the following of $K_{m}'' = 1.550 \times 10^{-5}$ M in the first case (line 2) and $K_{m}'' = 1.552 \times 10^{-5}$ M in the second case (line 1).

Experimental data of catalytic type of enzyme inhibition in literature there are.\textsuperscript{7,8,19,20} Now it becomes necessary to discuss the question of using the secondary ($1/V'; i$) coordinates of intersects for experimental data analysis on enzyme inhibition, which follows from transformation of Eq. (6) to Eq. (8) due to the equality $K_{m}'=K_{m}''$ of parameters characteristic of only this $III_i$ type of enzyme inhibition (Table 3, line 3).

---

\textbf{Non-existence of secondary coordinates of intersects}

Section C-Research paper

**Example 3**

Calculation of $K_{m}''$ constant of enzyme inhibition. Let us use the data obtained at study of the inhibitory effect of potassium ferrocyanide K$_3$Fe(CN)$_6$ on initial rates of pNPP cleavage catalyzed by porcine alkaline phosphatase (EC 3.1.3.1) for calculation of $K_{m}''$ constants of enzyme inhibition. The enzyme is produce of Sigma (USA).

The concentration of pNPPP in the experiment was varied within $0.294 \times 10^{-5} - 0.98 \times 10^{-5}$ M, the concentration of enzyme was kept constant $1.13 \mu$g mL$^{-1}$. The other conditions are the same as in Example 1.
It becomes evident from analysis of the Eqns. 6, 7 and 8 of the text that (1/V'; i) coordinates of slopes for calculation of $K_{II}$ intersects coordinates of intercepts for calculation of $K_{III}$ reaction parameters, and as the coordinates of slopes for calculation of $K_{II}$ slope constants of this type of enzyme inhibition, but not $K_{II}$ intersect constants of biparametric types of enzyme inhibition characterized by change of only one $V'$ reaction parameter, and as the course of change of $K_{m}'$ parameters of such reactions shall not be taken into account.

Examples of simultaneous use of the coordinates of slopes and intersects for calculation of $K_{II}$ slope constants and $K_{II}$ intersect constants of biparametrical types of enzyme inhibition are numerous in literature.6-11,17,18

Besides, the authors do not discuss the question that, what does the value of $K_{II}$ constant of enzyme inhibition characterize, if $K_{II}$ constant is attached the sense of constant of dissociation of the enzyme-inhibitor complex, especially in those cases, when their values do not coincide? This question can be put in another way that, could one and the same inhibitor exhibit different binding to enzyme under the same experimental conditions?

Probably, not. The situation gets simplified at refusal of calculation and using symbols of $K_{II}$ intersect constants of enzyme inhibition, because they are the $K_{II}$ constants of enzyme inhibition, But then, the necessity of using symbols of $K_{II}$ slope constants of enzyme inhibition is also of no use, and only one symbol remains – it is the $K_{II}$ constant of enzyme inhibition (for the convenience, it is preferable to indicate the type of inhibited reaction). It is analogous in enzyme activation (Tables 3 and 2).
